

Oliver Smith (Refactored using the techniques suggested and wrote the mini report)

1. Extract Variable: Added a private '`__add_tax()`' method to return a value with the `self.tax_threshold` added to it instead of having this buried in another function. I know the observable behaviour has not changed as I have created a new function that replaces a code block in one specific place. The test results also do not change. The benefit of creating this function is that it improves readability for the '`generate_report`' method, and also creates a reusable method that can be used elsewhere in the code.

2. Parameterise Function: Updated the '`add_purchase()`' method so that it now accepts both lists and single elements, effectively combining both the '`add_purchase`' and '`add_purchases`' functions into one. I know the function has not changed as the tests still run correctly afterwards (I also tested it by hand as I wanted to focus on refactoring rather than writing tests)

3. Inline Variable: Moved and simplified a complex if tree in the '`generate_report`' function to improve readability and make the code simpler.
